F	Predictors of moving among winners	29

A. DEVIATIONS FROM THE PRE-ANALYSIS PLAN

After the pre-analysis plan was filed, the survey was shortened in order to make sure respondents were paying attention throughout its duration. Several questions on the following topics were cut:

- Expenditure on education
- Psychological well-being
- Belief in market values
- The expenditures for which borrowing occurred

As a result, I am unable to report effects on these outcomes.

Also, I had planned on a) using a split-sample strategy to select hypotheses for testing as recommended by Anderson and Magruder 2017 and Olken 2015 and b) reporting effects for indices of outcomes. I had intended to take these steps to reduce the number of hypotheses tested and therefore decrease the number of multiple-testing adjustments required. Instead, I tested all of the hypotheses reported in the pre-analysis plan and made multiple-testing adjustments within families of hypotheses; this choice should lead to more conservative p-values.

I also do not report heterogeneous effects on income group, lottery year, and whether the lottery building is in the same ward as the original home due to insufficient power to detect these effects.

B. EFFECTS ON INCOME, ASSETS, AND BORROWING

Respondents were generally unable to provide numbers for monthly earnings, but preferred to provide ranges instead. Enumerators thus placed respondents into income bins. The bins used, unfortunately, appear to not capture the full range of the income distribution but rather only the left tail. Even so, a rightward shift in the distribution shows that winners clearly are earning more than non-winners. The p-value for a KS-test comparing these two distributions is 0.001.

Figure B.I: The reported income distribution for winners and non-winners. Bars represent the frequency of households in each income bin

Winning households do not appear to be consuming more durable assets than non-winning households (Figure B.II). They do not appear more likely to own common components of many asset-based indices of wealth, such as computers and dining tables

(Davila et al. 2014), even while control group ownership of these items is not particularly high (Table IV).

I also asked individuals a multiple choice question about the sources to which they would turn when faced with a shock such as a family illness. Winners are about 5 percentage points more likely to report turning to commercial banks or credit unions, but the effect is no longer statistically significant after correcting for multiple hypothesis testing.

Figure B.II: Treatment effects on asset ownership and reported likelihood of visiting commercial banks for loans.

Treatment effects for loan activity are based on multiple choice responses to “If you have a financial emergency (such as an illness in the family), where do you think you will get the money?” Questions were open-ended, with the enumerator filling out the correct categories. “Informal lender” includes local politicians or leaders. Bars show 90% and 95% confidence intervals. P-values (with with p-values using a Benjamini-Hochberg correction for the false discovery rate in parentheses) are shown on the right. Full regression output with and without covariate adjustment available in Tables E.XII-E.XIV.

C. BALANCE TESTS

Table C.I: Caste/occupation category codes

Code	Category
AR	Artist
CG	Central govt. servant occupying staff qrts.
DF	Families of defense personall
DT	Denotified tribes
EX	Ex-servicemen and dependents
FF	Freedom fighters
GP	General public
JR	Journalists
ME	MHADA employees
MP/MLA/MLC	Ex-members of parliament, legislative assemblies, legislative councils
NT	Nomadic tribes
PH	Handicapped persons
SC	Scheduled castes
SG	State government employees who have retired
ST	Scheduled tribes

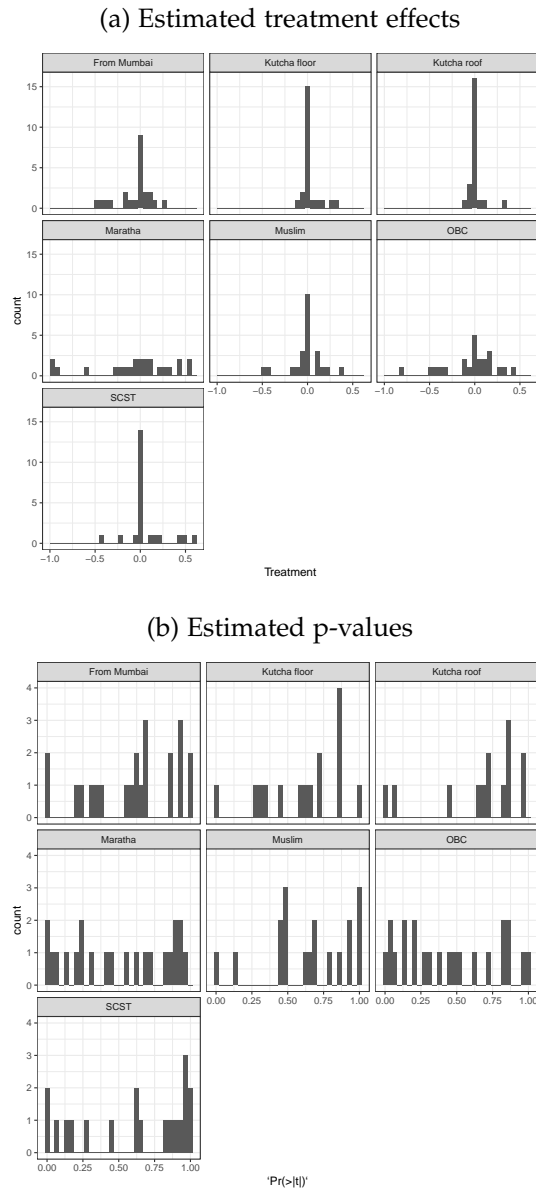

Table C.II: Proportion of members of each category in treatment and control groups after mapping with p-values for difference in proportions test.

Figure C.I: Distribution of (a) treatment effects and (b) p-values of those tests on fixed characteristics across Mumbai's 24 administrative wards. The Treatment effect estimated is the difference between winning and non-winning households estimated through an OLS regression of each variable on indicators for winning the lottery. Each regression includes an interaction with the centered block-level indicator for randomization groups. All regressions include HC2 errors.

I also conduct balance tests *within* each of Mumbai's municipal wards. The indicator for being from the same ward as the one in which the lottery is held is removed here. One ward (A) is dropped due to low sample size. Figure C.I presents the distribution of the 24 estimated treatment effects along with the estimated 24 p-values. Consistent with the null hypothesis, the distributions of the estimated treatment effects appear roughly centered at 0, and the p-curves appear to take on a roughly uniform distribution.

Table C.IV: Regression of treatment indicator on the covariates

Covariates ¹	Winning the housing lottery
OBC	-0.053 (0.057)
SCST	0.060 (0.071)
<i>Maratha</i> caste member	-0.041 (0.046)
Muslim	0.002 (0.066)
<i>Kutcha</i> ² floor	0.200 (0.118)
<i>Kutcha</i> ² roof	-0.277 (0.124)
From Mumbai	-0.003 (0.047)
From the same ward as the apartment building	0.051 (0.061)
Block dummies?	Yes
F Statistic (df = 91; 742)	1.2046
N	834
R ²	0.120
Adjusted R ²	0.015

¹ Unless otherwise specified, all covariates are dummy variables.

² "*Kutcha*" means "raw" or "impermanent." Variable measured at time of application through recall.

Table C.V: Treatment effects on age by cohort.

Cohort	Control	Treatment	sd
<i>Turned₆</i>	9.454	-0.067	0.227
<i>Turned₁₆</i>	19.228	-0.107	0.340
<i>Turned₁₈</i>	21.175	-0.242	0.308
<i>Turned₂₁</i>	23.638	-0.099	0.218
Older	44.859	0.259	0.505

The “Control” column presents means for winning households. The “Treatment” column presents the difference between winning and non-winning households estimated through an OLS regression of each variable on indicators for winning the lottery. All models include standard errors clustered at the household level and the treatment indicator interacted with mean-centered block dummies. “*Turned_x*” is an indicator for membership in the cohort of individuals that completed X years of age in between the lottery and being surveyed, using age_t , or each individual’s oldest possible age. “Older” is an indicator for being in the cohort of individuals older than 21 at the time of the lottery.

D. RESULTS USING ALTERNATIVE AGE INDICATOR

Table D.I: Regressions of individual completion of various years of education on the treatment indicator.

	Dependent variable:								
	Years of education	I(>0 years)	I(>0 years)	I(>10 years)	I(>10 years)	I(>12 years)	I(>12 years)	I(=15 years)	I(=15 years)

R ²	0.033	0.047	0.049	0.053	0.098	0.051	0.121	0.058	0.112
Adjusted R ²	0.007	0.005	0.007	0.012	0.010	0.017	0.082	0.018	0.073

All models include standard errors clustered at the household level and the treatment indicator interacted with mean-centered block dummies. "*Turned*_X" is an indicator for whether the individual completed X years of age in between the lottery and being surveyed, using *age*_L, or each individual's oldest possible age. "Older" is an indicator for an individual being older than 21 at the time of the lottery.

Table D.II: Regressions of individual employment on the treatment indicator.

Adjusted R ²	0.055	0.031	0.026	0.020	0.018	0.047

Part-time employment is defined as working fewer than five days a week. All models include standard errors clustered at the household level and the treatment indicator interacted with mean-centered block dummies. "*Turned*_X" is an indicator for whether the individual completed X years of age in between the lottery and being surveyed, using *age_l*, or each individual's oldest possible age. "Older" is an indicator for an individual being older than 21 at the time of the lottery.
